Three necessary conditions for Darwinian evolution are:

1. Multiplication,
2. Variation, and
3. Selection.

Variation through mutation and recombination operates on the genotype whereas the phenotype is the target of selection.

One important property of the Darwinian scenario is that variations in the form of mutations or recombination events occur uncorrelated with their effects on the selection process.

All conditions can be fulfilled not only by cellular organisms but also by nucleic acid molecules in suitable cell-free experimental assays.

$$dx_i / dt = f_i x_i - x_i \Phi = x_i (f_i - \Phi)$$

which even in its simplest forms always appears to be associated with living matter (i.e. multimolecular systems, such as the living cell). As a consequence of the exciting discoveries of "molecular biology", a common version of the above question is: Which came first, the protein or the nucleic acid? This question is often referred to as the "chicken-and-the-egg" problem. The term "first" is usually meant to define a causal rather than a temporal relationship, and the words "protein" and "nucleic acid" may be substituted by "function" and "information". The question in this form, when applied to the interplay of nucleic acids and proteins as presently encountered in the living cell, leads ad absurdum, because "function"

I. Introduction

I.1. "Cause and Effect"

The question about the origin of life often appears as a question about "cause and effect". Physical theories of macroscopic processes usually involve answers to such questions, even if a statistical interpretation is given to the relation between "cause" and "effect". It is mainly the theory of evolution which has led many scientists believe that our present physics does not offer any obvious explanation for the existence of life,

The Hypercycle

A Principle of Natural Self-Organization

Part A: Emergence of the Hypercycle

Manfred Eigen

Max-Planck-Institut für biophysikalische Chemie, D-3400 Göttingen

Peter Schuster

Institut für theoretische Chemie und Strahlenchemie der Universität, A-1090 Wien

This paper is the first part of a trilogy, which comprises a detailed study of a specific type of functional organization and determines its relation with the origin of life. The second part will be concerned with the properties of the hypercycle. Self-replicating macromolecules, such as RNA or DNA, in a suitable environment exhibit a behavior, which we may call Darwinian and which can be formally represented by the concept of quasi-species. A quasi-species is seen as a group of nearly identical macromolecules, each with nearly identical properties. Assisted by one or several (degenerate) enzyme copies. External constraints enforce the selection of the best adapted distribution, commonly referred to as the wild-type. Most important is the Darwinian selection, as it is the first step of the process. If these criteria are violated, the information used in the nucleic sequence of the master copy will disappear irreversibly leading to an error catastrophe. As a consequence, selection and evolution of RNA and DNA will be lost. In the third part of the trilogy, the properties of information can be stored in a single replicative unit. An analysis of experimental data regarding RNA and DNA replication at various levels of organization reveals, that a sufficient amount of information for the building of a hypercycle can be gathered only by the action of several different replicative units (or reproductive cycles) through successive stages. A stable functional integration will raise the system to a new level of organization and thereby increase its information capacity considerably. The hypercycle appears to be such a form of organization,

hypercyclic organizations are able to fulfill these requirements. Non-cyclic linkages among the autonomous reproduction cycles, such as chains or branched, tree-like networks are devoid of such properties.

The mathematical methods used for proving these assertions are fixed-point, Lyapunov- and trajectory analysis in higher-dimensional phase spaces, spanned by the concentration coordinates of the competing species. The self-organizing properties of hypercycles are elucidated, being analyzed as well as numerical techniques.

Preview on Part C: The Realistic Hypercycle

A realistic model of a hypercycle relevant with respect to the origin of the genetic code and the translation machinery is presented. It is based on the assumption of a minimal model system:

- (1) The hypercycle has a sufficiently complex structure to admit an organization with finite probability under preexisting conditions.
- (2) It permits a continuous emergence from closely interrelated RNA-like precursors, originally being members of a stable RNA-exchange pool and having been amplified to a level of abundance.
- (3) The organizational structure and the properties of single functional units of this hypercycle are still reflected in the present genetic code and the translation apparatus of the prokaryotic cell, as well as in certain bacterial viruses.

I. The Paradigm of Unity and Diversity in Evolution

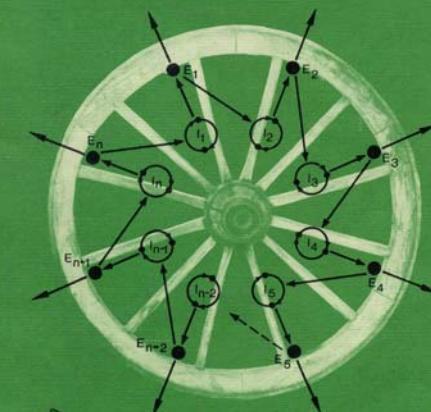

Why do millions of species, plants and animals exist, while there is only one basic molecular machinery of the cell: one universal genetic code and unique characteristics of the macromolecules?

The geneticists of our day would not hesitate to give an immediate answer to the first part of this question. Diversity of species is the outcome of the tremendous branching process of evolution with its myriads of single steps of reproduction and mutation. It im-

- random individuals. The primer pair used for genomic DNA amplification is 5'-TCTCCCTGGATCT-CATTAA-3' (forward) and 5'-TCTTTGCTTCCTG-TCCACCC-3' (reverse). Reactions were performed in 25 μ l using 1 unit of Tag DNA polymerase with each primer at 0.4 μ M; 200 μ M each dATP, dTTP, dGTP, and dCTP; and PCR buffer [10 mM tris-HCl (pH 8.3), 50 mM MgCl_2 , 1.5 mM MgCl_2] in a cycle condition of 94°C for 1 min and then 35 cycles of 94°C for 30 s, 55°C for 30 s, and 72°C for 30 s followed by 72°C for 6 min. PCR products were purified (Qiagen), digested with Xba I, and separated in a 2% agarose gel.
32. A nonsense mutation may affect mRNA stability and result in degradation of the transcript [L. Maquat, *Am. J. Hum. Genet.* **59**, 279 (1996)].
 33. Data not shown; a dot blot with poly(A)⁺ RNA from 50 human tissues (The Human RNA Master Blot, 7770-1, Clontech Laboratories) was hybridized with a probe from exons 29 to 47 of *MYO15* using the same condition as Northern blot analysis (3).
 34. Smith-Magenis syndrome (SMS) is due to deletions of 17p11.2 of various sizes, the smallest of which includes *MYO15* and perhaps 20 other genes ([6]; K.-S. Chen, L. Potocki, J. R. Lupski, *MRDD Res. Rev.* **2**, 122 (1996)]. *MYO15* expression is easily detected in the pituitary gland (data not shown). Haplodeficiency for *MYO15* may explain a portion of the SMS phenotype such as short stature. Moreover, a few SMS patients have sensorineural hearing loss, possibly because of a point mutation in *MYO15* in trans deletion.
 35. R. A. Fridell, data not shown.
 36. K. B. Avraham et al., *Nature Genet.* **11**, 369 (1995); X.-Z. Liu et al., *ibid.* **17**, 268 (1997); F. Gibson et al., *Nature* **374**, 62 (1995); D. Weil et al., *ibid.*, p. 60.
 37. RNA was extracted from cochlea (membranous labyrinth) obtained from human fetuses at 18 to 22 weeks of development in accordance with guidelines established by the Human Research Committee at the Brigham and Women's Hospital. Only samples without evidence of degradation were pooled for poly(A)⁺ selection over oligo(dT) columns. First-strand cDNA was prepared using an Advantage RT-for-PCR kit (Clontech Laboratories). A portion of the first-strand cDNA (4%) was amplified by PCR with Advantage DNA polymerase mix (Clontech Laboratories) using human *MYO15*-specific oligonucleotide primers (forward, 5'-GCATGACCTGCCGGCTAAAT-GGG-3'; reverse, 5'-CTCACCGCTTCTGCATGGT-GCTGCCGTGG-3'). Cycling conditions were 40 s at 94°C; 40 s at 66°C (3 cycles), 60°C (5 cycles), and 55°C (29 cycles); and 45 s at 68°C. PCR products were visualized by ethidium bromide staining after fractionation in a 1% agarose gel. A 688-bp PCR product is expected from amplification of the human *MYO15* cDNA. Amplification of human genomic DNA with this primer pair would result in a 2903-bp fragment.
 38. We are grateful to the people of Bengkala, Bali, and the two families from India. We thank J. R. Lupski and K.-S. Chen for providing the human chromosome 17 cosmid library. Continuity in Evolution: On the Nature of Transitions

Walter Fontana and Peter Schuster

To distinguish continuous from discontinuous evolutionary change, a relation of nearness between phenotypes is needed. Such a relation is based on the probability of one phenotype being accessible from another through changes in the genotype. This nearness relation is exemplified by calculating the shape neighborhood of a transfer RNA secondary structure and provides a characterization of discontinuous shape transformations in RNA. The simulation of replicating and mutating RNA populations under selection shows that sudden adaptive progress coincides mostly, but not always, with discontinuous shape transformations. The nature of these transformations illuminates the key role of neutral genetic drift in their realization.

A much-debated issue in evolutionary biology concerns the extent to which the history of life has proceeded gradually or has been punctuated by discontinuous transitions at the level of phenotypes (1). Our goal is to make the notion of a discontinuous transition more precise and to understand how it arises in a model of evolutionary adaptation.

We focus on the narrow domain of RNA secondary structure, which is currently the simplest computationally tractable, yet realistic phenotype (2). This choice enables the definition and exploration of concepts that may prove useful in a wider context. RNA secondary structures represent a coarse level of analysis compared with the three-dimensional structure at atomic resolution. Yet, secondary structures are empirically well defined and obtain their biological and biochemical importance from being a scaffold for the tertiary structure. For the sake of brevity, we shall refer to secondary structures as "shapes." RNA combines in a single molecule both genotype (replicable sequence) and phenotype (selectable shape), making it ideally suited for *in vitro* evolution experiments (3, 4).

To generate evolutionary histories, we used a stochastic continuous time model of an RNA population replicating and mutating in a capacity-constrained flow reactor under selection (5, 6). In the laboratory, a goal might be to find an RNA aptamer binding specifically to a molecule (4). Although in the experiment the evolutionary end product was unknown, we thought of its shape as being specified implicitly by the imposed selection criterion. Because our intent is to study evolutionary histories rather than end products, we defined a target shape in advance and assumed the replication rate of a sequence to be a function of

the similarity between its shape and the target. An actual situation may involve more than one best shape, but this does not affect our conclusions.

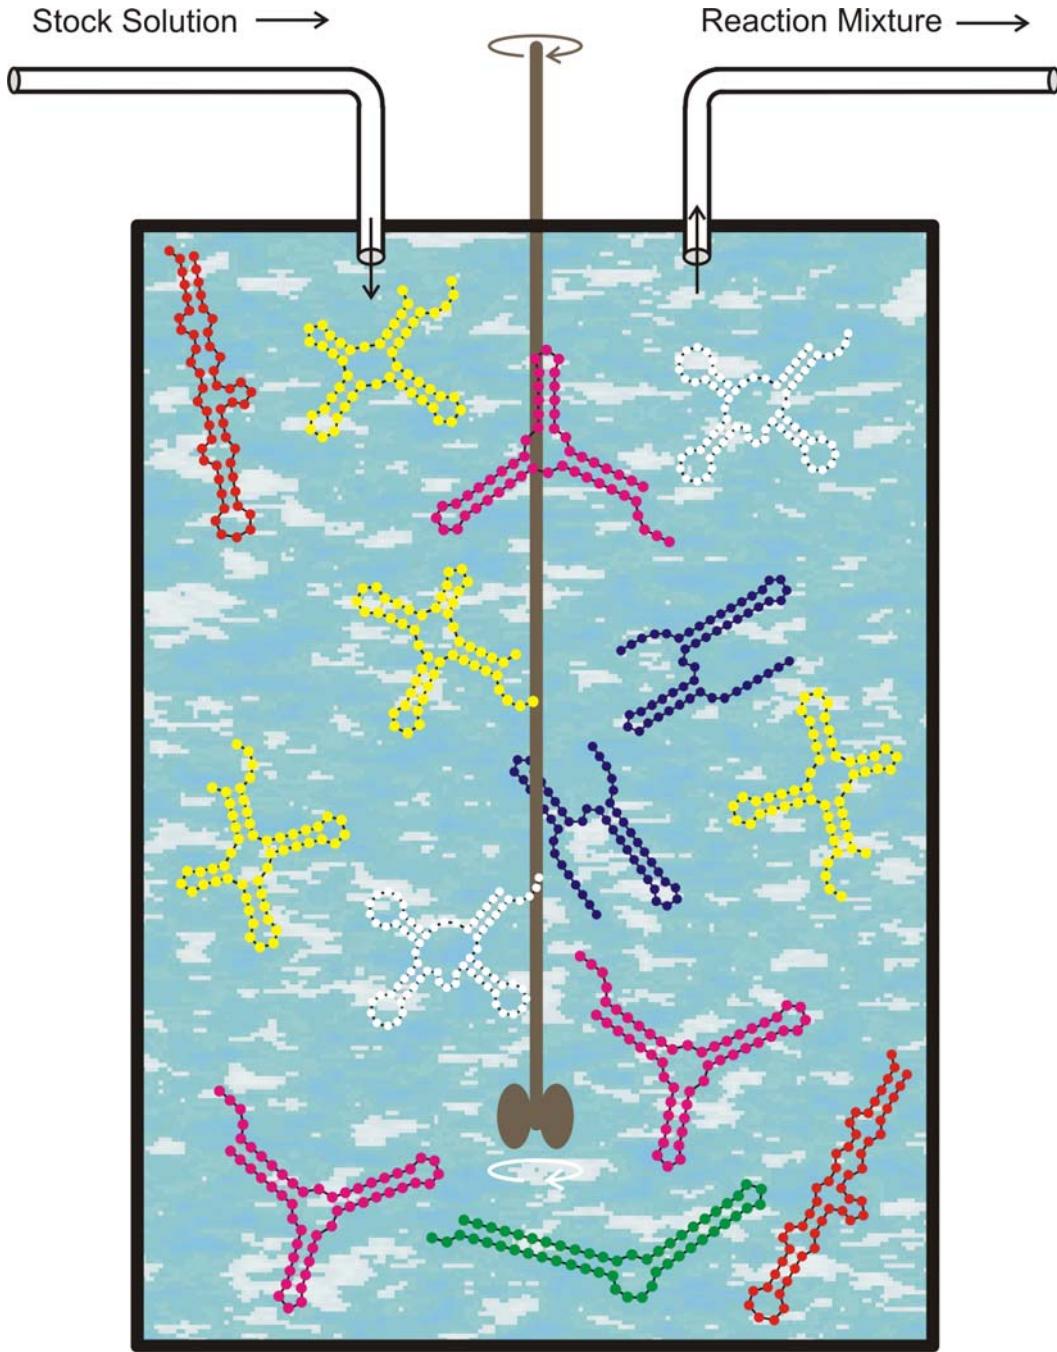

An instance representing in its qualitative features all the simulations we performed is shown in Fig. 1A. Starting with identical sequences folding into a random shape, the simulation was stopped when the population became dominated by the target, here a canonical tRNA shape. The black curve traces the average distance to the target (inversely related to fitness) in the population against time. Aside from a short initial phase, the entire history is dominated by steps, that is, flat periods of no apparent adaptive progress, interrupted by sudden approaches toward the target structure (7). However, the dominant shapes in the population not only change at these marked events but undergo several fitness-neutral transformations during the periods of no apparent progress. Although discontinuities in the fitness trace are evident, it is entirely unclear when and on the basis of what the series of successive phenotypes itself can be called continuous or discontinuous.

A set of entities is organized into a (topological) space by assigning to each entity a system of neighborhoods. In the present case, there are two kinds of entities: sequences and shapes, which are related by a thermodynamic folding procedure. The set of possible sequences (of fixed length) is naturally organized into a space because point mutations induce a canonical neighborhood. The neighborhood of a sequence consists of all its one-error mutants. The problem is how to organize the set of possible shapes into a space. The issue arises because, in contrast to sequences, there are

One Sequence, Two Ribozymes: Implications for the Emergence of New Ribozyme Folds

Erik A. Schultes and David P. Bartel*

We describe a single RNA sequence that can assume either of two ribozyme folds and catalyze the two respective reactions. The two ribozyme folds share no evolutionary history and are completely different, with no base pairs (and probably no hydrogen bonds) in common. Minor variants of this sequence are highly active for one or the other reaction, and can be accessed from prototype ribozymes through a series of neutral mutations. Thus, in the course of evolution, new RNA folds could arise from preexisting folds, without the need to carry inactive intermediate sequences. This raises the possibility that biological RNAs having no structural or functional similarity might share a common ancestry. Furthermore, functional and structural divergence might, in some cases, precede rather than follow gene duplication.

Related protein or RNA sequences with the same folded conformation can often perform very different biochemical functions, indicating that new biochemical functions can arise from preexisting folds. But what evolutionary mechanisms give rise to sequences with new macromolecular folds? When considering the origin of new folds, it is useful to picture, among all sequence possibilities, the distribution of sequences with a particular fold and function. This distribution can range very far in sequence space (*I*). For example, only seven nucleotides are strictly conserved among the group I self-splicing introns, yet secondary (and presumably tertiary) structure within the core of the ribozyme is preserved (2). Because these dis-

tant isolates have the same fold and function, it is thought that they descended from a common ancestor through a series of mutational variants that were each functional. Hence, sequence heterogeneity among divergent isolates implies the existence of paths through sequence space that have allowed neutral drift from the ancestral sequence to each isolate. The set of all possible neutral paths composes a "neutral network," connecting in sequence space those widely dispersed sequences sharing a particular fold and activity, such that any sequence on the network can potentially access very distant sequences by neutral mutations (3–5).

Theoretical analyses using algorithms for predicting RNA secondary structure have suggested that different neutral networks are interwoven and can approach each other very closely (3, 5–8). Of particular interest is whether ribozyme neutral networks approach each other so closely that they intersect. If so, a single sequence would be capable of folding into two different conformations, would

have two different catalytic activities, and could access by neutral drift every sequence on both networks. With intersecting networks, RNAs with novel structures and activities could arise from previously existing ribozymes, without the need to carry non-functional sequences as evolutionary intermediates. Here, we explore the proximity of neutral networks experimentally, at the level of RNA function. We describe a close apposition of the neutral networks for the hepatitis delta virus (HDV) self-cleaving ribozyme and the class III self-ligating ribozyme.

In choosing the two ribozymes for this investigation, an important criterion was that they share no evolutionary history that might confound the evolutionary interpretations of our results. Choosing at least one artificial ribozyme ensured independent evolutionary histories. The class III ligase is a synthetic ribozyme isolated previously from a pool of random RNA sequences (9). It joins an oligonucleotide substrate to its 5' terminus. The prototype ligase sequence (Fig. 1A) is a shortened version of the most active class III variant isolated after 10 cycles of *in vitro* selection and evolution. This minimal construct retains the activity of the full-length isolate (*I*). The HDV ribozyme carries out the site-specific self-cleavage reactions needed during the life cycle of HDV, a satellite virus of hepatitis B with a circular, single-stranded RNA genome (*II*). The prototype HDV construct for our study (Fig. 1B) is a shortened version of the antigenic HDV ribozyme (*II*), which undergoes self-cleavage at a rate similar to that reported for other antigenic constructs (13, 14).

The prototype class III and HDV ribozymes have no more than the 25% sequence identity expected by chance and no fortuitous structural similarities that might favor an intersection of their two neutral networks. Nevertheless, sequences can be designed that simultaneously satisfy the base-pairing requirements

6. Die DNA + Protein Welt
7. **Evolutionsmechanismen**

Darwins Theorie wurde in folgenden Punkten **voll bestätigt**:

- Das **Auftreten von Varianten** bei der Reproduktion wurde durch die Aufklärung der molekularen Mechanismen von Rekombination und Mutation auf eine solide wissenschaftliche Basis gestellt.
- Das Darwinsche **Prinzip der Optimierung durch Variation und Selektion** in endlichen Populationen gilt nicht nur in der Biologie sondern auch in der unbelebten Welt.
- Die natürliche Entstehung der Arten und die daraus resultierenden **phylogenetischen Stammbäume** wurde durch die Vergleiche der genetischen Informationsträger heute lebender Organismen voll bestätigt.

Darwin hatte in folgenden Punkten **nicht recht**:

- Der Darwinsche Vererbungsmechanismus war falsch. Mendel hatte die korrekte Lösung.
- Mutation und Rekombination können keine, kleine und große Auswirkungen haben und es besteht kein Grund, dass die biologische Evolution quasikontinuierlich oder anders ausgedrückt nur in verschwindend kleinen Schritten erfolgt.
- Im Verlaufe der biologischen Evolution gab es auch katastrophenartige Ereignisse terrestrischen und extraterrestrischen Ursprungs.
- Die Komplexität der höheren Lebewesen ist so groß, dass ihre Eigenschaften nicht voll optimiert sein können.
- Es gibt Phasen der biologischen Evolution, welche mit Hilfe des Darwinschen Mechanismus von Variation und Selektion nicht verstanden werden können, da sie die auf Kooperation von Konkurrenten beruhen.
